ABUNDANCE OF ELEMENTS

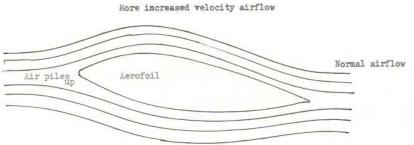

Graph of relative abundances of elements in the solar system, and probably in the universe. These were discovered, in the case of the lighter elements, using the Sun's spectra, and with the heavier ones, meteorites.

The 8 most common elements in the Earth's oceans, atmosphere, and uppermost 10 miles of curst.:

Oxygen	62.6 %
Silicon	21.2 %
Aluminium	6.5%
Sodium	2.64 %

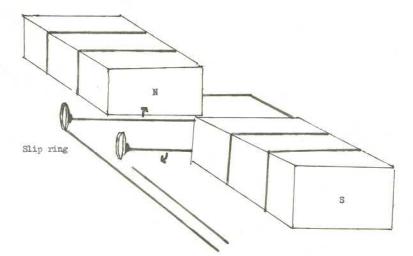

AEROFOIL

Increased velocity airflow

According to hydrodynamics, the sum of energies of velocity and pressure, and the potential energy of elevation remain constant. As the energy of an air mass is the sum of its velocity and pressure, it follows that if there is an increase in velocity, the pressure falls and vice-versa. As the distance over the top of an aerofoil is greater than that under the bottom, and the two airflow reach the end of the aerofoil at the same time, it follows that the upper one has more velocity and less pressure, and the lower; one less velocity and more pressure. The differential has a lifting effect on the body and is called 'lift'. Where the air meets behind the aerofoil, there is a higher pressure, due to the two streams hitting each other. This tends to push the aerofoil forward. At the front, however, as air hits the aerofoil, the aerofoil is retated slightly. The high velocity of airflow under the wing helps to keep the wing or aerofoil up as well. ALTERNATING CURRENT

Generation:

Alternating current changes its direction of flow at a fixed rate. The most common type used is that from the mains, which is reversed 120 times a second, thus it has a frequency of 60 c.p.s.. The cheif advantage which alternating current has over direct current is that its voltage can be changed much more easily. A.C. is generated by an alternator, which, in its simplest form is a wire or coil rotating in an electric field between two opposing poles of a magnet. The current is drawn by means of two slip rings which are brushed by copper brushes from the coil.

BAROMETERS

In the mercury barometer, a tube isv filled up with mercury, and then inverted into a bath of mercury. This causes a vaccuum at the top of the tube, so the mercury rises according to how much atmospheric pressure there is on the bath.

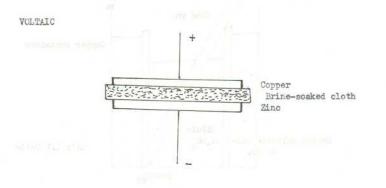

In the aneroid barometer, the force of the atmospheric pressure on the flexible wall of the vaccuum container, gauses it to move up and down. By a pointer, this is shown a a circular scale, after being mechanically amplified.

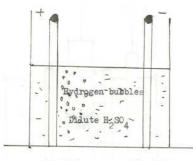

Aneroid type

BATTERIES

SIMPLE CELL

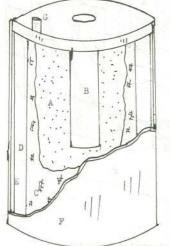

Cu plate

Zn plate

The disadvantage of this type of cell is that the Hydrogen gas does not conduct and thus, when there is a lot of electrolysis, the cell fails to work so efficiently. This is called potarization.

20	Very quiet room.

Eyepiece

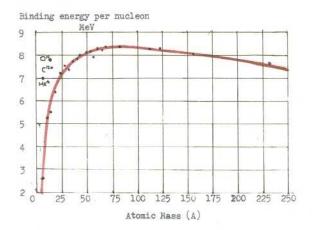

Prism binoculars are ingenious because they allow the objective to have a long focal length without the binoculars having to be very long in tube length. They also produce an erect and laterally correct image. Prism A corrects the Vertical inversion from the objective, and prism B corrects the Lateral inversion.

The nickel strips resistance varies with temperature, and so do the phosphor bronze support wires. Thus, the amount of heat falling on the bolometer can be deduced.

BONDING ENERGY

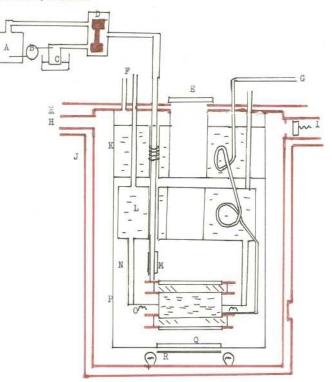

Graph of $\Delta(A,Z)c^2 / A$

It is reasonable to say that the binding energy between the parts of a nucleus is about 8 MeV.

CIRCUIT DIAGRAM SYMBOLS

The light primaries work by addition, e.g. the three primaries make white, whereas the pigment primaries work by subtraction. If you have a red piece of paper, then it absorbs all light except red. Thus, it is obvious why the pigment primaries are complementaries to the light primaries.

Light mixing.

This occurs when the slit is in the region of the wavelength of the the waves. As the wave tries to push through the hole it is 'bent'. This accounts for sound being heard 'round a corner'.

N.B. The nearest shell to the nucleus is K and then L, and so on.

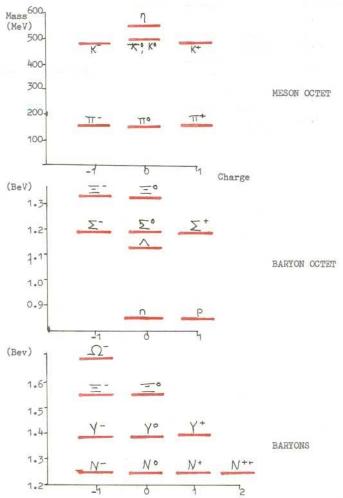

ELECTRON MICROSCOPE

The reflected beam of electrons is then put through a series of magnetic lenses which serve to spread it out up to a magnification of IOO,000 X, and the stream of electrons fall on a fluorescent screen which produces a image. The reflected X-Rays can be used spectroscopically to determine the constituents of the specimin. One of the advantages of an electron microscope is that it has a field of view and depth of view 300 times better than a light microscope. ELEMENTRY PARTICLES

In the Atomic Weights, 1 equals 1/12 of the weight of Carbon isotope I2.

ENERGY.

There are seven forms of energy: Kinetic, Potential, Heat, Electrical, Chemical, Radiant. and Atomic. Out of these, only one can exist on its own in space: Radiant energy. All the others need some sort of medium, or come from matter itself, like Atomic energy. Energy is described as the ability to do work. In the natural world, except for a few cases where matter is turned into energy and vice-versa, no energy can be destroyed or created in the universe. Thus we arrive at the law of the conservation of energy . This law states that whatever energy transfers take place . no energy can ever be lost. We will now take an example of an energy chain. We will start at the sun which is 'Driven ' by atomic energy . The exact method will be discussed later , this produces radiant energy in the form of light and heat . This light then falls onto a photoelectric cell which converts it into electrical energy . This electrical energy is then used to electrolise a chemical solution turning its chemical energy into heat . Thus we have used up all the types of energy known . Nearly all the energy on this earth originates from the sun e.g. fossilised fuels etc. . but a very small amount e.g. volcanoes originate from the earth itself. It is possible to convert any given type of energy to any other except for a very few combinations . These include radiant to kinetic and atomic to kinetic and electrical . There is another type of energy inherent in the very structure of the universe as we know it at present. This is a store of energy which has not yet been tapped by man. It exists as the combination between matter and anti-matter . When an atom and an anti-atom meet a considerable amount of energy is produced , a radiation called annihilation radiation and total annihilation of both particles takes place. This is the only time when $e = mc^2$ is truly valid. Before going into the different types of energy it is worthy saying that, as we go on, all the energy in this universe is gradually being turned into heat which then diffuses into the cosmos. This entropy is called the heat death of the universe, and is discussed from another angle in another article. We will start with heat energy . This energy comes in the form of the kinetic energy of molecules in a substance . The more they move around , the more heat energy the substance is said to have . There are three methods by which heat can be transferred between two things . n.b. it is impossible in nature for heat to be transferred between a cold body which already has the heat and a hot body .

GEIGER COUNTER.

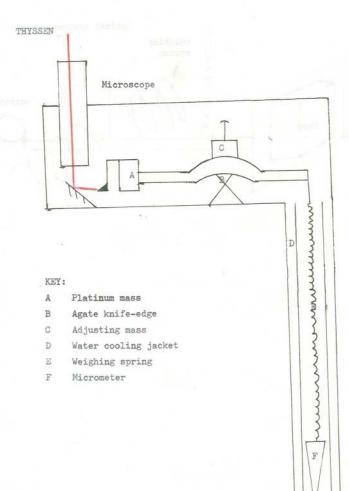

(Geiger-Mueller Tube)

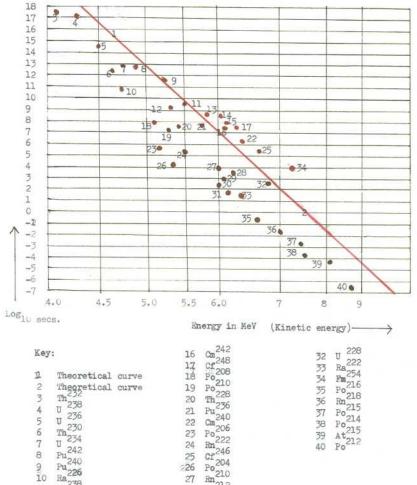

High-Tension Source

The low pressure gas is usually Argon, with a tough of Alcohol vapour in. The pressure is maintained at about 5 mm. Mg.. When an alpha, beta, or gamma particle passes between the anode and the cathode, positive ions and electrons are produced in equal numbers. The potential difference between the anode and the cathode beigg very high (IOOO volts), the electrons quickly collect on the anode wire, causing an electrical pulse which is amplified and then displayed visually or surally. The positive ions slowly diffuse onto the cathodé.

When the reflector is placed at the crest or through of the wave, the resultant reflected wave is coincident with the original, thus doubling the amplitude. this is called CONSTRUCTIVE INTERFERENCE.

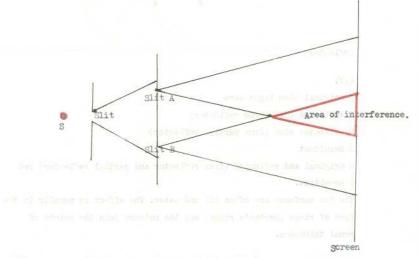

If the reflector is half-way between the crest and trough of the wave, then the crest of the reflected wave is co-incident with the trough of the original and vive-versa, thus meaning that the two waves cancell each other out, leaving nothing. This is called DESTRUCTIVE INTERFERENCE.

The A on each digram represents the anti-node, and the N the node. The node is the point at which the three waves meet, and the antinode is the point where they are fatthest spart.

Lloyd's mirror. Interference using a reflector.

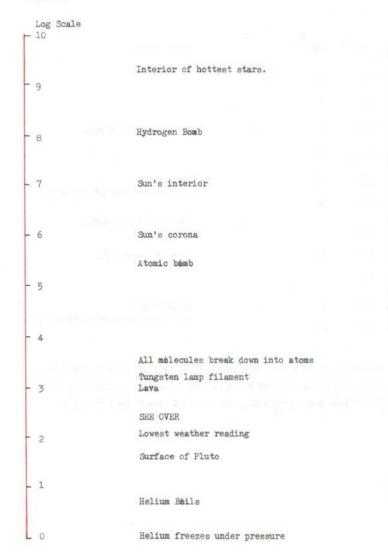

This is a practical method of demonstrating the two source interference pattern.

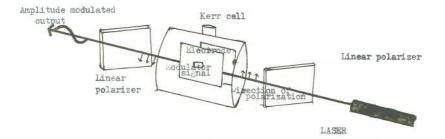

Ionization potential means the energy needed to free one electron from the nucleus.

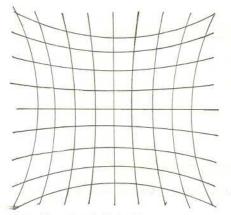

KELVIN.

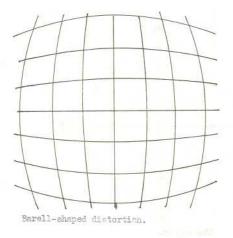

12 1.77

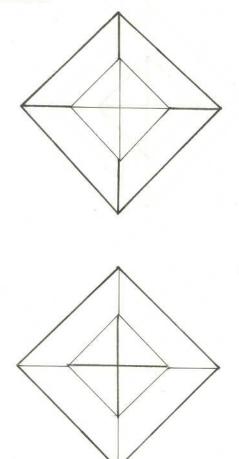

The Kerr effect is that, when polarized light passes through a medium like nitrobenzene to which a high potential differance is applied, the direction of polarization is changed. Thus if there is a large potential differance in the liquid, the direction of polarization is rotated so that it is impossible for it to get through a second polarizer. This effect occurs in times of down to 10^{-8} seconds. Thus it is used for high speed shutters and as a means of modulating a LASER beam.

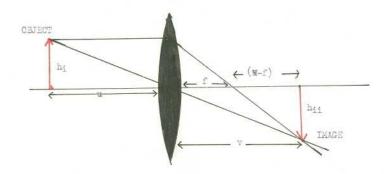

Pincushion-shaped distortion.

LENS ASTIGMATISM.

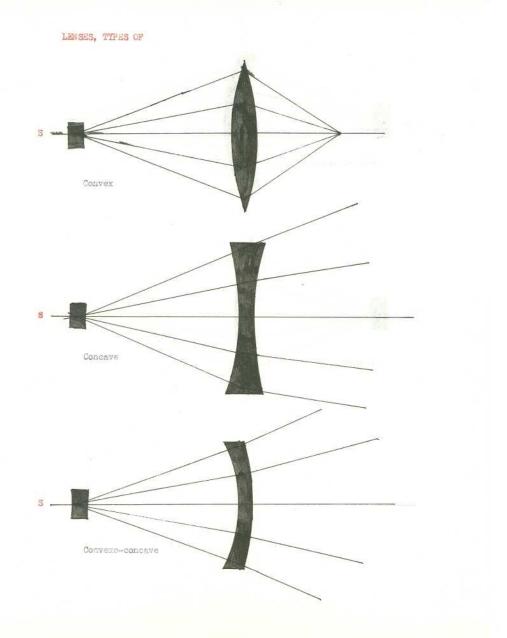

$$\frac{h_{\underline{i}}}{h_{\underline{i}\underline{i}}} \quad \text{equals} \; \frac{f}{(v-f)}$$

$$\frac{h_1}{h_{11}}$$
 equals $\frac{u}{v}$

 $\frac{1}{u} \quad \frac{1}{v} \quad \frac{1}{v} \quad \frac{1}{f}$

LIGHT, INTENSITY OF

The solid angle of space surrounding a given is 4- units, thus one unit is about 8 % (exactly 7.963 %). The luminous intensity of a light source is described as the luminous flux (flow) emitted per unit solid angle, or the luminous energy emitted per unit solid angle per second. However, experiment shows that the amount of energy produced by a filament is not equal all over a shhere, but depends on the direction of the filament. The unit of light intensity is the Candela (cd). This is described as the luminous intensity of liquid platinum under certain conditions. A 60 - watt bulb has a mean luminous intensity of about 50 cd. The luminous effeciency of a light source is described as lumens per watt. A lumen is the luminous flux emitted by a source of 1 cd in 1 unit solid angle. An 100 W tungsten (Wolfram) filament lamp has a luminous effeciency of 15 lumens per watt. The intensity of illumination of a surface is described as the luminous flux per unit area incident on it. Luminous intensity refers to a source, illumination to a receiving body. The lux is the illumination around a point P on a surface when a light of 1 cd is 1 metre from the point P in a perpendicular direction. A minimum illumination of 150 lux for libriares. 300 for offices, and 3000 for industry using micro-components, is recommended.

Illumination E equals Luminous intensity I over distance d squared.

$$E = \frac{I}{d^2}$$

From an average of relaible results, the velocity of light (c) is now held to be: 29979250000 cms/sec.

Thus, in one year light travels: 94542562800000000 cms Light travels 887544.052654 times as fast as sound. Light from the Sun takes 496.333304 secs or 8,272388 mins to reach Earth. Light from the moon takes 0.948656 secs to reach Earth.

If the electron moves back to its original orbit in steps, then the steps further away from the nucleus will give off less energy, than the ones near it, due to the fact that the electron is further from the attraction of the nucleus. The wavelength of the light emited, as $E = \frac{hc}{l}$ the wavelength of the light is greater on the steps further away from the nucleus.

RADIOMETER

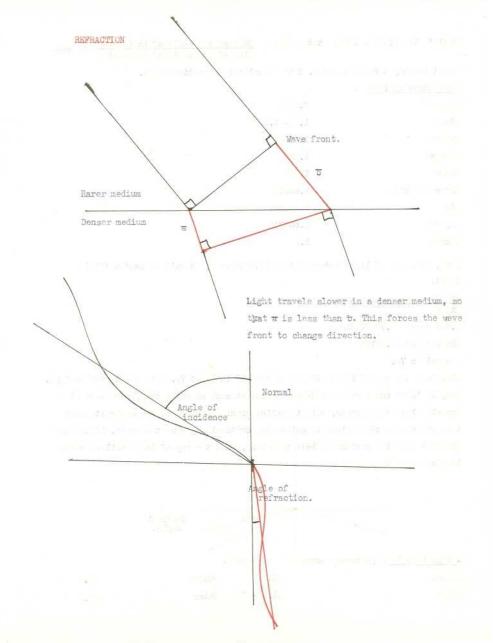

Basically, this instrument works because the black side of the vane absorbs the heat, and the light silvered reflects it, so that it stays cool. Due to a process called 'Thermal Transpiration' more gas molecules collect on the black sides, when the bulb is heated, so that there is pressure. This forces the vanes to turn clockwise, but when the bulb is cooled, the process is reversed, and the vanes retate counter-clockwise.

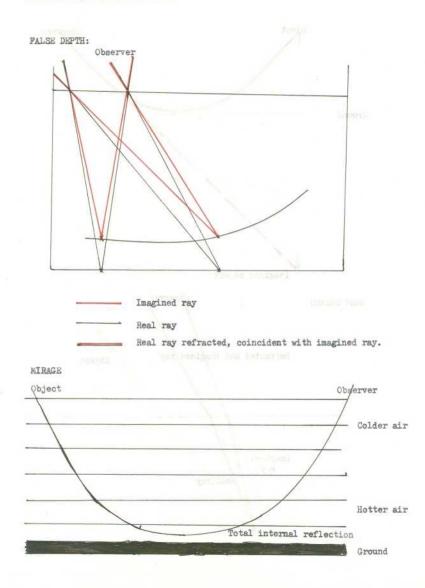

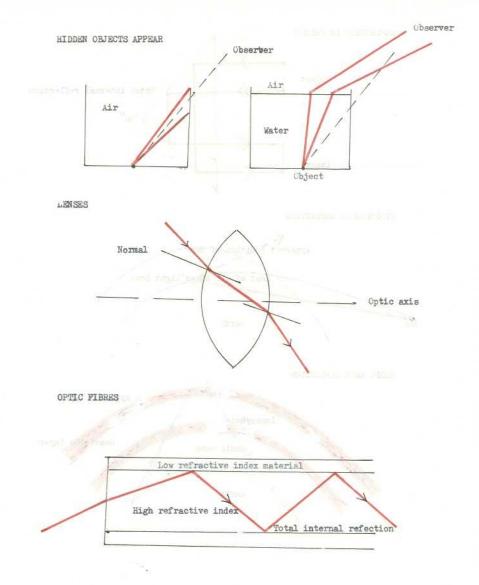

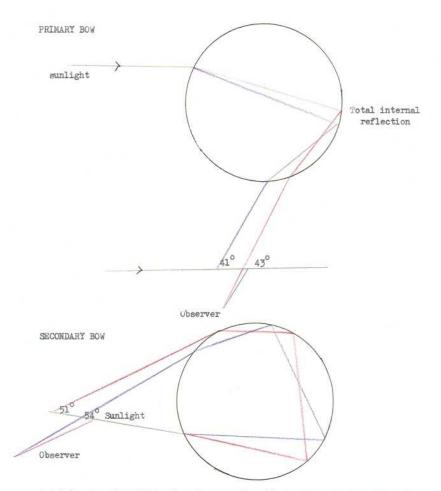

Mirror

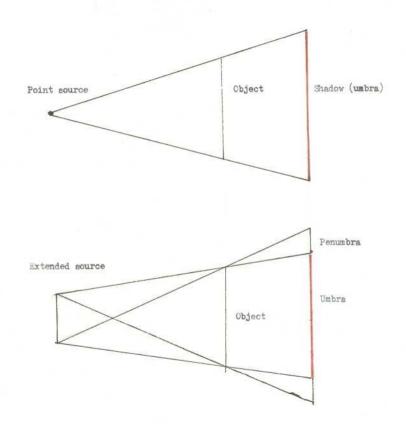

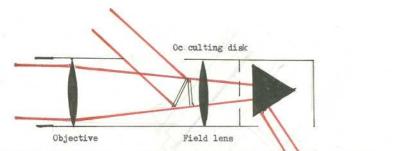

A rainbow is only visible directly away from the Sun because the rainbow is too faint compared with the sun. 10 % of the rain droplets have double internal reflection, so that a secondary bow is very faint.

Picture A Picture B

The two pictures apperar superimposed and thus 3 - dimensional.

VECTOGRAPH

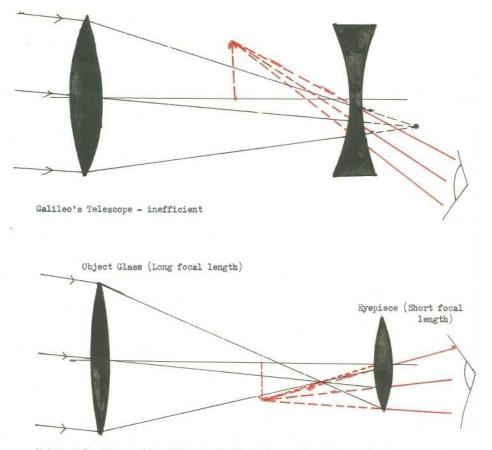

Two sheets of polaroid with their easy-axes marked an top of each other. Behind each sheet there is a picture on transparent film. Both pictures are of the same thing, but from different angles. The easy-axes of the polaroids are not at 90° otherwise the picture behind the second polaroid would never be visible.

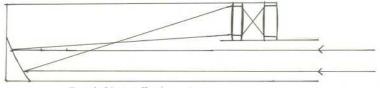

Left eye

Right eye

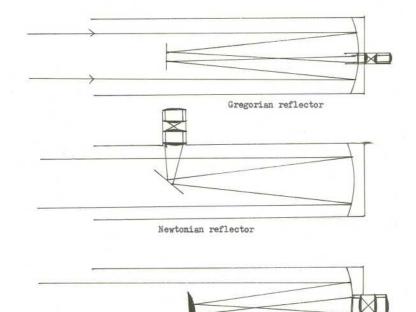

At 90° to the behind polaroid, so that ghe picture the back one is not visible to this eye. However, the picture behimd the front one is visible. At 90° to the front polaroid, so that only the picture behind the back one is visible.

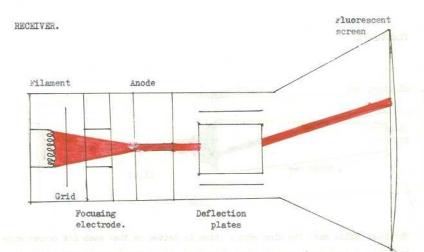

Modern refractor - quite efficient, but it is impossible for practical reasons to make for telescope, very large lenses. To re-invert the image in the astronomical refractor for terrestrial work, an auxiliary lens can be inserted at 2f from the image formed by the objective.

Herschelian reflector

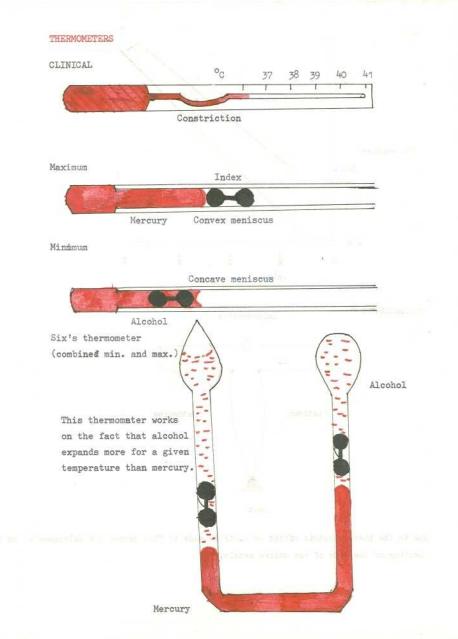

Cassegrainian reflector.

The filament produces a stream of electrons (called a cathode ray) which are attracted to the anode, and then race on through the deflection plates which, being of negative charge, deflect the now positive electrons. These plates deflect the rays so that it traverses the screen, which is made of a fluorescent material which gives off light when an electrical charge hits it, 405 or 625 times a second, thus leaving a bright trail. During each line, the intensity of the beam is varied to give light and dark, thus producing

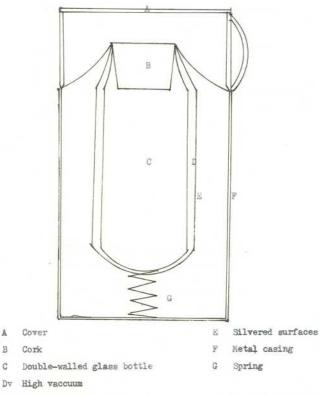

Graph of the speed of the dot while traversing a line and returning to its starting point.

В

C

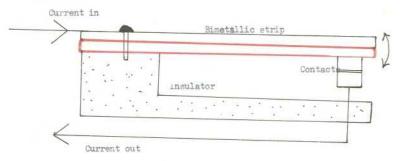

The vaccum prevents heat coming to the contents of the bottle by convection or conduction, and the silvered surfaces by radiation.

Gas out

Invar is an alloy of steel which contains 36 % of bickel. It expands on $1/1000\ 0000$ of its length per degree Centigrade. When the brass tube expands it pushes its joiner to the invar bar to the left, and thus the invar bar pulls the valve closer so that the gas flow is reduced. The opposite happend when the temperature falls.

ELECTRICITY

At a certain temperature the bimetal bend so that the contacts break away from each other, and close when under that temperature.

UNIVERSE, Nature of

According to Euclidean geometry, the angles of a triangle add up to I80°, and the proof of this is perfectly valid. But, take a triangle drawn on the surface of a sphere, the shortest distance between two points on the surface of the sphere is curved. Thus we find that the angles of a triangle here add up to slightly more than I80°. This was proved in I823 by a man called Gauss who used surveying equipment to measure the triangle made by Brocken, Hohehagen, and Inselberg in Germany. The longest side in the triangle is about I60 kms.. He measured the interior angles

86[°]13'58.366" 53[°]64'5.642"

as:

40°39'30.165"

180 00'14.173"

He realized that if space was curved, then the three angles of a triangle taken on a much larger scale, would total much more than I80°. The question is: How do you mea-ure distances in space when we are stuck within our solar system? When Pluto's orbit was predicted, using its effect gravitation-wise on other planets, the error was found to be small. If the radius of curvature of the universe was small, then a significant error would have been discovered. As there was almost no error, it is certain that the radius of curvature of the universe is not less than 5 x 10¹⁷ cms... Another method of proving t e curvature of space was suggested by Schwarzschild. This was called the trigonometrical parallax. In this method, observations of a star were taken 6 months apart. The angle made between the line joining Earth to the Sun and Earth to the distant star were measured at each time. We will call these two angles a and b. On a flat sur ace, or, in this case, in flat space, a plus b is less than 180. So far as we know, this is true out until the limits of our present observations. at 3 x 10²⁰ cms.. Therefore, we might conclude that the radius of curvature of the universe was bigger than this, which is not neccessarily true, because some of our measures of distance, assume that space is flat. But, by triangulation. we know that the radius of the universe must be greater than 10²⁸ cms.. With this distance is accosiated the charecteristic LENGTH of the universe, but is this the radius of the radius of curvature of the universe ? This is one of the major problems confronare many theories of the universe, but all have one thing in common, they all accept the fact that the universe is expanding at a considerable rate. The proof of this comes in the doppler effect, which is discussed in another chapter. However, there is one possible paradox. That is that the galaxies all seem to be moving away from our galaxy, which is obviously untrue. What is obviously happening is that the distances between the galaxies are being increased, making it look as if all the galaxies are going away from us. The nearer galaxies are receding slowly, but the most distant ones which we have seen are receding at speeds of up to $\frac{1}{2}$ the velocity of light. There are two main theories of the universe which are worth discussing: The Big Bang, or Superdense theory, and the Solid State theory. The Superdense or Big Bang theory postulates that there was an original single Superdense mass of energy and matter, which exploded. Thus the galaxies are fragment of this original 'bomb' and are flying outwards at a high speed. The fact that the universe is expanding means that its radius is also doing so. The other theory is the Solid State theory. This postulates that the universe started to expand with very little matter in it except hydrogen, but that as gaps are left by receding galaxies, these are filled in and the hydrogen fusions to produce all the other elements we know of. This would explain the fact that hydrogen is by far the most abundant element in the universe. Now I must explain the death of the universe. The expansion which we detect must come to an end when the first galaxies recedes at the velocity of light. because this speed is unachievable. We have good reason to believe that the speed of recession is increasing as time goes on, so this point must finally come. The other 'fying' factor in the universe is that all energy finally unwinds itself down to heat, so it is thought that eventually, this may be the only form of energy in the universe.
